# Algorithm Design

Algorithm to build a binary decision tree using *CART*. In this example, we show a model to predict whether or not to go shopping, according to weather.

# Node Splitting

As an example, this split is based on the condition “punt\_ingles > 50.”

For this case weighed Gini impurity is 0.38.

As an example, this split is based on the condition “Fam\_numlibros == “0 A 10 LIBROS”.”

For this case weighed Gini impurity is 0.48.

# Algorithm Complexity

For the third deliverable

Create the table in Powerpoint. Do not  
copy pixelated screenshots from the  
technical report please!

|                    | Time Complexity    | Memory Complexity |
|--------------------|--------------------|-------------------|
| Training the model | $O(N^2 * M * 2^M)$ | $O(N * M * 2^M)$  |
| Testing the Model  | $O(N * M)$         | $O(1)$            |

Time and memory complexity of the (In this semester, one could be CART, ID3, C4.5... please choose) algorithm. (Please explain what do N and M mean in this problem. PLEASE DO IT!)

Explain the tables in your own words

Include another HD picture related to the example that you modeled in the decision tree

# Decision-Tree Model

Keep this title

Complete this slide  
For the third deliverable

A binary decision tree to predict Saber Pro scores based on the results of Saber 11. Violet nodes represent those with a high probability of success, green medium probability and red a low probability of success.

Explain the Figures in your own words

Create the Figure in Powerpoint. Do not copy pixelated screenshots from the technical report please!

## Most Relevant Features

Social Studies

English

Gender

Use an icon for each feature!

Is it ethical to make a model that predicts academic success based on gender?

# Evaluation Metrics

Keep this title

Complete this slide  
For the third deliverable

Use these  
Colors for  
Your figures

How many selected  
items are relevant?

$$\text{Precision} = \frac{\text{true positives}}{\text{true positives} + \text{false positives}}$$

How many relevant  
items are selected?

$$\text{Recall} = \frac{\text{true positives}}{\text{true positives} + \text{false negatives}}$$

Explain Accuracy too...  
In the same manner

If possible, avoid equations for  
simple concepts that can be  
explained through diagrams

# Evaluation Metrics

C. Patiño-Forero, M. Agudelo-Toro, and M. Toro. Planning system for deliveries in Medellín. ArXiv e-prints, Nov. 2016. Available at: <https://arxiv.org/abs/1611.04156>

Include a  
screenshot

The screenshot shows the arXiv.org page for the paper 'Planning system for deliveries in Medellín'. The header includes the Cornell University logo and the text 'Cornell University'. Below this is the arXiv.org navigation bar with the path 'arXiv.org > cs > arXiv:1611.04156'. The main title is 'Planning system for deliveries in Medellín' and the authors are 'Catalina Patiño-Forero, Mateo Agudelo-Toro, Mauricio Toro'. The abstract states: 'Here we present the implementation of an application capable of planning the shortest delivery route in the city of Medellín, Colombia. We discuss the different approaches to this problem which is similar to the famous Traveling Salesman Problem (TSP), but differs in the fact that, in our problem, we can visit each place (or vertex) more than once. Solving this problem is important since it would help people, especially stores with delivering services, to save time and money spent in fuel, because they can plan any route in an efficient way.' The page also includes metadata: 'Comments: 5 pages, 9 figures', 'Subjects: Data Structures and Algorithms (cs.DS)', 'ACM classes: F.2.0; G.2.2', and 'Cite as: arXiv:1611.04156 [cs.DS] (or arXiv:1611.04156v1 [cs.DS] for this version)'.
